Return Value	Function Name	Description
bool	getNextSession	Returns false when there is no more session; true otherwise
string	getFileName	Returns file name for the EventData
map<string, string>	getSessionInformation	Returns the map. Keys are UserID, ApplicationID, CumulativeSessionNumber, StartTime, and Duration.
map<string, vector<string>>	getSessionEventData	Returns the map. Keys are EventName and EventTiming. The values of EventTiming vector are in the unit of 10th of a second converted from unsigned integer to string.

Figure 12B

Return Value	Function Name	Description
bool	getNextLine	Returns one line of string data as an out parameter string. The function returns true if there is a line; false if no more line exists with empty string.
string	getFileNameWithSuffix	Returns file name for the data with suffix if applicable

```
void CMonitorManager::stopMonitoring()
{
	TRACE("CMonitorManager::stopMonitoring \n");

//  1.  calls the function stopMonitoring() of
//      CUsageLogger.
	m_UsageLogger.stopMonitoring();

//  2.  calls the function getEventData() of
//      CUsageLogger.  This function returns the usage
//      information, CAbsEventData, to CMonitorManager.
	CAbsEventData * loc_pAbsEventData = m_UsageLogger.getEventData();

//  3.  calls the function getFormatAndProtocolVector()
//      of CFormatProtocol_InformationBase.  This function
//      returns the following to CMonitorManager: an int for
//      the data format, a list<int> for the communication
//      protocols, and a bool to indicate if the return
//      values (format and protocol) are valid.

	int loc_nFormat;
	list<int> loc_ProtocolVector;

	CProcessorBuilder loc_ProcessorBuilder;

	while(m_FormatProtocol_InformationBase.getFormatAndProtocolVector(
		loc_nFormat, loc_ProtocolVector)){

//  4.  calls the function createDataFormatProcessor()
//      of CProcessorBuilder.  CMonitorManager passes an
//      int for the data format into this function.  This
//      function returns the data format processor,
//      CAbsDataFormatter, to CMonitorManager.

		CAbsDataFormatter * loc_pAbsDataFormatter =
			loc_ProcessorBuilder.createDataFormatProcessor(loc_nFormat);

//  5.  calls the function formatEventData() of
//      CAbsDataFormatter.  CMonitorManager passes the
//      usage information, CAbsEventData, into this
//      function.  This function returns the formatted
//      usage information, CAbsFormattedEventData, to
//      CMonitorManager.

		CAbsFormattedEventData * loc_pAbsFormattedEventData =
			loc_pAbsDataFormatter->formatEventData(loc_pAbsEventData);

//  6.  calls the function createProtocolProcessor() of
//      CProcessorBuilder.  CMonitorManager passes an int
//      for the communication protocol into this function.
//      The int is the first int from the protocol vector,
//      list<int>.  This function returns the protocol
//      processor, CAbsProtocolProcessor, to CMonitorManager.

		for(list<int>::iterator loc_ProtocolVectorIterator =
		   loc_ProtocolVector.begin();  loc_ProtocolVectorIterator NE
		    loc_ProtocolVector.end(); loc_ProtocolVectorIterator ++){
```

3.3 CProcessorBuilder Class Specification

3.3.1 Function List

```
public:
  CProcessorBuilder();
  ~CProcessorBuilder();
  CAbsDataFormatter* createDataFormatProcessor(int in_nFormat);
  CAbsProtocolProcessor* createProtocolProcessor(int in_nProtocol);

private:
  void initDataFormatProcessorMap();
  void initProtocolProcessorMap();
```

Include the following functions to create the different data format processors and protocol processors.

```
  CAbsDataFormatter* createCommaDataFormatter();
  CAbsDataFormatter* createXMLDataFormatter();
  CAbsProtocolProcessor* createSmtpProtocolProcessor();
  CAbsProtocolProcessor* createFtpProtocolProcessor();
```

If new data formats or new protocols are added, then new functions to create them must be added.

Include the following typedef declarations for the functions that create the data format processors and protocol processors.

```
  typedef CAbsDataFormatter* (*DataFormatProcessorBuilder) ();
  typedef CAbsProtocolProcessor* (*ProtocolProcessorBuilder) ();
```

3.3.2 Class Attributes

Type	Attribute Name	Description
CAbsDataFormatter*	m_pDataFormatter	This attribute member points to the data format processor object. It is initialize to 0 in the constructor and the data format processor object is created by the function createDataFormatProcessor(). This function may be called multiple times so that it must delete the previous data format processor object pointed to by this attribute member before creating a new one. The destructor will delete the last data format processor object pointed to by this attribute member.
map<int, DataFormatProcessorBuilder>	m_ProtocolProcessorMap	This attribute member is a map of pointers to functions that create the data format processor. The key to this map is an int for the data format type. The value is a pointer to a function that creates the data format processor corresponding to the key. The pointers to the functions in the map are initialized in the function initDataFormatProcessorMap().
map<int, pair<CAbsProtocolProcessor*, ProtocolProcessorBuilder> >	m_ProtocolProcessorMap	This attribute member is a map of pointers to protocol processor objects and pointers to functions that create them. The key to this map is an int for the protocol processor type. The value is a pair consisting of a pointer to the protocol processor object and a pointer to a function that creates the protocol processor object. All the pointers to the protocol processor object are initialized to 0 and its corresponding functions are intialized by the function initProtocolProcessorMap(). The protocol processor objects are created by the function createProtocolProcessor(). The destructor will delete all the protocol processor objects pointed to by the map.

Figure 18A

```
3.3.3    Function Definitions
////////////////////////////////////////////////////////////////////////
// Function:          CProcessorBuilder
// Description:       Constructor
// Preconditions:     None.
// Postconditions:    None.
// Algorithm:         1.  calls the private function
//                    initDataFormatProcessorMap().
//                    2.  calls the private function
//                    initProtocolProcessorMap().
////////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////////
// Function:          ~CProcessorBuilder
// Description:       Destructor
// Preconditions:     None.
// Postconditions:    None.
// Algorithm:         1.  delete the object pointed to by m_pDataFormatter.
//                    2.  iterate through the map, m_ProtocolProcessorMap.
//                    For each entry in the map, get the protocol
//                    processor object pointed to by the pair and delete
//                    the object.
////////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////////
// Function:          createDataFormatProcessor
// Description:       This function creates a data format processor
//                    object.  The data format processor object created
//                    corresponds to the data format type in_nFormat.
// Preconditions:     The data format type must be valid.
// Postconditions:    The pointer to the data format processor object,
//                    m_pDataFormatter, cannot be 0.
// Algorithm:         1.  if m_pDataFormatter currently points to a data
//                    format processor object, then delete the object.
//                    2.  creates a new data format processor object by
//                    calling the function in the map,
//                    m_DataFormatProcessorMap, that corresponds to the
//                    data format type, in_nFormat, and assign it to
//                    m_pDataFormatter.
//                    3.  returns m_pDataFormatter.
////////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////////
// Function:          createProtocolProcessor
// Description:       This function creates a protocol processor object.
//                    The protocol processor object created corresponds
//                    to the protocol type in_nProtocol.
// Preconditions:     The protocol type must be valid.
// Postconditions:    The pointer to the created protocol processor object
//                    cannot be 0.
// Algorithm:         1.  for the protocol type, in_nProtocol, get the
//                    pair from the map that contains the pointer to
//                    protocol processor object and its corresponding
//                    pointer to the function that creates it.
//                    2.  if the pointer to the protocol processor object
//                    is 0, then use its corresponding function to create
//                    it and assign it to the pointer in the map.  Return
//                    the pointer to the protocol processor object.
//                    3.  if the pointer points to a protocol processor
//                    object, then return this pointer.
////////////////////////////////////////////////////////////////////////
```

Figure18B

```
////////////////////////////////////////////////////////////////////////
// Private
// Function:          initDataFormatProcessorMap
// Description:       This function initializes all the function pointers
//                    in the map m_DataFormatProcessorMap.  If new data
//                    formats are added, then this function must be
//                    modified.
// Preconditions:     None.
// Postconditions:    None.
// Algorithm:         1.  add entries to the map, m_DataFormatProcessorMap,
//                    for each data format type.  The key will be the
//                    data format type and the value will be the pointer
//                    to the corresponding function that creates the
//                    data format processor.
//                    2.  for data format type 1, the function pointer
//                    points to createCommaDataFormatter().
//                    3.  for data format type 2, the function pointer
//                    points to createXMLDataFormatter().
////////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////////
// Private
// Function:          initProtocolProcessorMap
// Description:       This function initializes all the pairs of pointers
//                    in the map m_ProtocolProcessorMap.  If new protocols
//                    are added, then this function must be modified.
// Preconditions:     None.
// Postconditions:    None.
// Algorithm:         1.  add entries to the map, m_ProtocolProcessorMap,
//                    for each protocol type.  The key will be the
//                    protocol type and the value will be a pointer to
//                    the protocol processor object and a pointer
//                    to the corresponding function that creates the
//                    protocol processor.  All pointers to the protocol
//                    processor objects will be set to 0.
//                    2.  for protocol type 1, the function pointer
//                    points to createSmtpProtocolProcessor().
//                    3.  for protocol type 2, the function pointer
//                    points to createFtpProtocolProcessor().
////////////////////////////////////////////////////////////////////////

  bool getFormatAndProtocolVector(int & out_nFormat, list<int> & out_ProtocolVector);

private:
  void setDefaultFormatAndProtocol();
```

5.2.2 Class Attributes

Type	Attribute Name	Description
map<int, list<int> >	m_FormatProtocolVectorMap	The key is a format value, and the list is the list of protocol values associated to the key. Because subscripting [] is not needed in this implementation, list is used for the vector implementation. This map is used to return the necessary information for getFormatAndProtocolVector function Note: > > is > space > to distinguish from ">>" that is used by iostream.
map<int, list<int> >	m_ProtocolFormatVectorMap	The key is a protocol value, and the list is the list of format values associated to the key. Because subscripting [] is not needed in this implementation, list is used for the vector implementation. This map is used to modify the map above if the protocol can take only one format.
bool	m_bFirstGetCall	This flag is used to call the function in CProtocolRestrictionCheck. The constructor set this to be true. The function, getFormatAndProtocolVector, sets it to be false
map<int, list<int> >::iterator	m_FormatProtocolVectorMapIterator	Iterator used to iterate the map.
CFormatProtocolCombinationCheck	m_FormatProtocolCombinationCheck	This object is to check the combination of format and protocol
CProtocolRestrictionCheck	m_ProtocolRestrictionCheck	This object is to check the protocol restriction. Currently, the only restriction is if protocol can have only one format support.

5.2.3 Function Definitions

```
////////////////////////////////////////////////////////////////////
//Function:         CFormatProtocol_InformationBase
//Description:      Constructor
//Preconditions:    None
//Postconditions:   None
//Algorithm:        Set m_bFirstGetCall to true
////////////////////////////////////////////////////////////////////
```

Figure 17A
23A

```
////////////////////////////////////////////////////////////////////
//Function:         ~CFormatProtocol_InformationBase
//Description:      Destructor
//Preconditions:    None
//Postconditions:   None
//Algorithm:        Default
////////////////////////////////////////////////////////////////////
```

```
////////////////////////////////////////////////////////////////
//Function:           storeFormatAndProtocol
//Description:        Check the passed format and protocol values
//                    to be valid or not.  If valid, store the
//                    values into the two maps
//Preconditions:      None
//Postconditions:     None
//Algorithm:          1. Send two values to check the combination
//                       through isFormatProtocolCombinationOK
//                       function.
//                    2. Check the return bool value.
//                    3. If yes, save format and protocol values
//                         into two maps  (Figure 5.4 of the
//                         Specification, Q6-DJ04-08)
//                       Else, do nothing.
////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////
//Function:           getFormatAndProtocolVector
//Description:        The function returns a format and a list
//                    of protocol values associated with the
//                    format through two parameters.  The function
//                    returns true if a format and list are
//                    returned, false otherwise.
//Preconditions:      None
//Postconditions:     The format value is within the range.
//                    The list is not empty and contains the values
//                    within the range.
//Algorithm:          1. If m_bFirstGetCall  (Figure 5.5 of the
//                          Specification Q6-DJ04-08)
//                       1.1 call the function to check the protocol
//                           restriction.
//                       1.2 check if m_FormatProtocolVectorMap is
//                           empty.  If empty, set it to default
//                           values of format and protocol by calling
//                           setDefaultFormatAndProtocol function.
//                       1.3 set the iterator to begin().
//                       1.4 set m_bFirstGetCall to be false
//                    2. If iterator is end, return false.
//                       else (Figure 5.6 of the Specification
//                             Q6-DJ04-08)
//                         got format and list to return and set
//                         return parameters.
//                         increment iterator.
//                         Return true.
////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////
//Private Function:   setDefaultFormatAndProtocol
//Description:        The function sets the default values for
//                    format and protocol in the map.
//Preconditions:      The m_FormatProtocolVectorMap is empty.
//Postconditions:     The map contains one default format and a
//                    protocol list with one default protocol.
//Algorithm:          Set the map with the default values.

5.4 CProtocolRestrictionCheck Class Specification

5.4.1 Function List

```
public:
   CProtocolRestrictionCheck();
   ~CProtocolRestrictionCheck()
   void getFormatProtocolVectorMapAfterCheckingProtocolRestriction
        (map<int, list<int> > & inOut_Map, const map<int, list<int> > & in_Map);

private:
   void initOneFormatRestriction();
   void oneFormatRestriction
        (map<int, list<int> > & inOut_Map, const map<int, list<int > > & in_Map);
```

5.4.2 Class Attributes

Type	Attribute Name	Description
vector<bool>	m_bOneFormatRestriction	Array size should be protocol size+1. The position corresponds to the protocol.

5.4.3 Function Definitions

```
////////////////////////////////////////////////////////////////////
//Function:          CProtocolRestrictionCheck
//Description:       Constructor
//Preconditions:     None
//Postconditions:    None
//Algorithm:         call initOneFormatRestriction
////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////
//Function:          ~CProtocolRestrictionCheck
//Description:       Destructor
//Preconditions:     None
//Postconditions:    None
//Algorithm:         Default
////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////
//Function:          getFormatProtocolVectorMapAfterCheckingProtocolRestriction
//Description:       Check the restriction on the protocol.
//                   Currently, there is only one possible restriction
//                   defined in the requirements.  If there are more
//                   restrictions, more private functions should be
//                   added and called.
//Preconditions:     None
//Postconditions:    None
//Algorithm:         1. Call oneFormatRestriction function
////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////
```

Figure 19A
25A

```
//Private Function:  initOneFormatRestriction
//Description:       This function initialize the attribute
//                   m_bOneFormatRestriction.  If more protocols are
//                   added, this initialization must be modified.
//Preconditions:     None
//Postconditions:    None
//Algorithm:         1. use assign(size+1,false) to initialize the
//                      vector to false.
//                   2. set the entries of true.
//                   Note: for class debug version, use
//                         ifdef and
//                         bool & pos1 = m_bOneFormatRestriction[1];
//                         bool & pos2 = m_bOneFormatRestriction[2];
//                         and so on to be able to see and to
//                         change the value.
////////////////////////////////////////////////////////////////////////

////////////////////////////////////////////////////////////////////////
//Private Function:  oneFormatRestriction
//Description:       This function receives two maps and if the one
//                   restriction is true for given protocol, the
//                   content of inOut_Map (m_FormatProtocolVectorMap)
//                   is adjusted accordingly.
//Preconditions:     None
//Postconditions:    None
//Algorithm:         Iterate over the in_Map (m_ProtocolFormatVectorMap)
//                   1. get the key (pkey)
//                   2. If m_bOneFormatRestriction[pkey]
//                      2.1 get the value list of in_Map for the key
//                      2.2 local int lastFormat = back(),
//                      2.3 iterate over the list
//                           if *iterator NE lastFormat
//                             iterate over inOut_Map[*iterator] list
//                                 if the value EQ pkey
//                                     erase the entry from the list
//                   3. Iterate over inOut_Map
//                        if value list is empty,
//                          erase the entry from inOut_Map
//--------------------------------------------------------------------
//Example:                          0 1 2 3 4
//   m_bOneFormatRestriction = [0,0,1,0,1]  (four protocols)
//                               0: false, 1: true
//   inOut_Map (m_FormatProtocolVectorMap)
//      = { 1, <1,2,3,4>                --> <1, 2, 3>
//          2, <2,1,3,4>                --> <1, 3>
//          3, <3,4,1,2>                --> <3, 4, 1>
//          4, <2,4>)                   --> <>
//   in_Map (m_ProtocolFormatVectorMap)
//      = (1, <1, 3, 2>
//         2, <4, 3, 2, 1>
//         3, <1, 3, 2>
